L'Agence internationale de l'énergie craint qu'après 2020 les capacités d'exploitation soient insuffisantes pour répondre à la hausse de la demande.

What does this mean to you?

Outline

**Energy
Stories**

**Modeling
the
Transition**

Energy stories

**About 1 million years ago:
Fire domestication: lighting, heating, cooking
->improved health**

**About 10 000 years ago:
Agriculture: a ‘new’ way to ‘efficiently’ collect solar
energy via photosynthesis**

During the Roman Empire, agriculture provided food to humans (some of them are slaves) and animals: this was (almost) the only source of energy

The Roman Empire in 117 AD

- Senatorial provinces
- Imperial provinces
- Client states

Well, the Romans used to have another source of energy...

During the Middle Ages, mills are deployed in Europe
1 mill corresponds to (about) 40 men in terms of power
- European GDP*2 between 1000 and 1500
- « Only » 30% in Asia during the same period

A famous example: the Dutch Golden Age (16th century)

- Efficient agriculture**
- Peat**
- Waterways**
- Trade, city development**
- Sawmills for boat construction**

« *Een Wonder en is gheen wonder* »
Simon Stevin

**Before using coal, 25 cubic meters of wood are needed
to produce 50 kg of iron
(in forty days, a forest is cleared on a radius of 1 km)**

In the UK, wood shortage leads to the discovery of the potential of coal

Coal made the massive development of metallurgy possible, leading to new infrastructures

After WW2, almost exponential growth of oil consumption opens the so-called « consumer society » era

In Western Europe, almost 5% GDP growth per year during 30 years

« The Glorious Thirty » - « Les Trente Glorieuses »

-> 1973 Oil Crisis

-> In Europe, emergence of public debt and mass unemployment

Trajectories of Societies

Energy & GDP

- Recent research in Economics has shown that:
 - The empirical elasticity (measured from time series among OECD countries over the last 50 years) of the consumption of primary energy into the GDP is about 60%, which is 10 times higher than what is predicted by the « *Cost Share Theorem* »

Elasticity can be quantified as the ratio of the percentage change in one variable to the percentage change in another variable

- There is a causality link between the consumption of primary energy and the GDP in the direction Energy -> GDP

Modeling the transition

ERoEI

- **ERoEI for « Energy Return over Energy Investment »** (also called EROI) is the ratio of the amount of usable energy acquired from a particular energy resource to the amount of energy expended to obtain that energy resource:

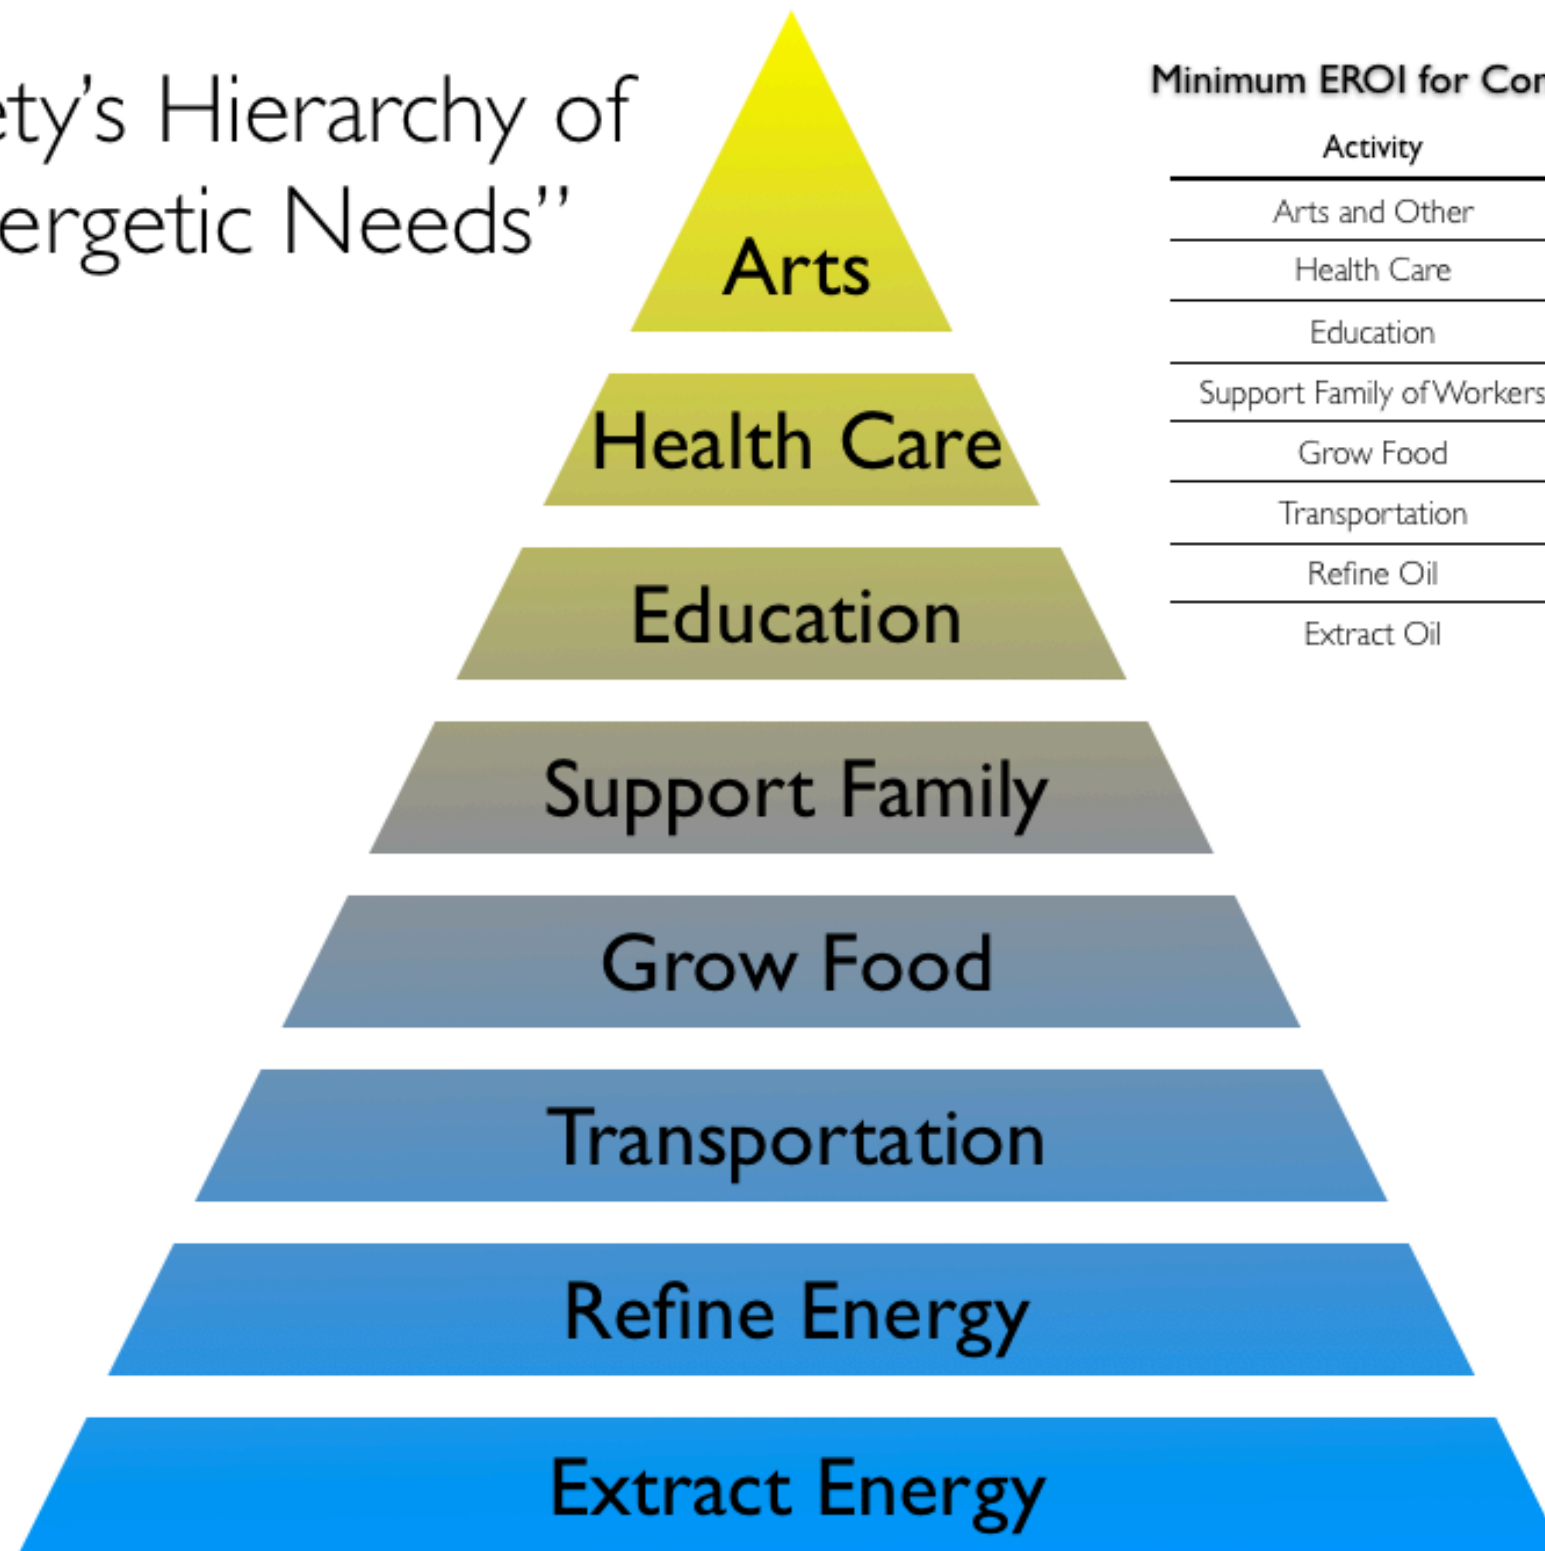

$$EROI = \frac{Usable\ Acquired\ Energy}{Energy\ Expended}$$

- The highest this ratio, the more energy a technology brings back to society
- Notation : 1:X

Source: EROI of Global Energy Resources - Preliminary Status and Trends - Jessica Lambert, Charles Hall, Steve Balogh, Alex Poisson, and Ajay Gupta State University of New York, College of Environmental Science and Forestry Report 1 - Revised Submitted - 2 November 2012 DFID - 59717

Society's Hierarchy of “Energetic Needs”

Minimum EROI for Conventional Sweet Crude Oil

| Activity | Minimum EROI Required |
|---------------------------|-----------------------|
| Arts and Other | 14 : 1 |
| Health Care | 12 : 1 |
| Education | 9 or 10 : 1 |
| Support Family of Workers | 7 or 8 : 1 |
| Grow Food | 5 : 1 |
| Transportation | 3 : 1 |
| Refine Oil | 1.2 : 1 |
| Extract Oil | 1.1 : 1 |

Modeling the transition

- A discrete-time model of the deployment of « renewable energy » production capacities
- Budget of non-renewable energy

$$\forall t \in \{0, \dots, T-1\}, B_t \geq 0$$

$$\exists r > 0, \exists \tau > 0, \exists t_0 \in \mathbb{R} : \forall t \in \{0, \dots, T-1\},$$

$$B_t = \frac{1}{r} \frac{e^{\frac{-(t-t_0)}{\tau}}}{\left(1 + e^{\frac{-(t-t_0)}{\tau}}\right)^2}$$

Modeling the transition

- Set of renewable energy production technologies:

$$\forall n \in \{1, \dots, N\}, \forall t \in \{0, \dots, T - 1\}, R_{n,t} \geq 0$$

- Characteristics $\Delta_{n,t} \geq 0$

$$ERoEI_{n,t} \geq 0$$

- Deployment strategy

$$R_{n,t+1} = (1 + \alpha_{n,t})R_{n,t} \quad \alpha_{n,t} \in [-1, \infty[$$

Modeling the transition

- Energy costs for growth and long-term replacement

$$\forall n \in \{1, \dots, N\}, \forall t \in \{0, \dots, T - 1\},$$

$$C_{n,t}(R_{n,t}, \alpha_{n,t}) \geq 0 \quad M_{n,t} \geq 0$$

- Total energy and net energy to society

$$\forall t \in \{0, \dots, T - 1\}, E_t = B_t + \sum_{n=1}^N R_{n,t}$$

$$S_t = E_t - \left(\sum_{n=1}^N C_{n,t}(R_{n,t}, \alpha_{n,t}) + M_{n,t} \right)$$

Modeling the transition

- Constraint on the quantity of energy invested for energy production

$$\forall t \in \{0, \dots, T - 1\},$$

$$\exists \sigma_t : C_{n,t}(R_{n,t}, \alpha_{n,t}) + M_{n,t} \leq \frac{1}{\sigma_t} E_t$$

Modeling the transition

- Further assumptions
 - Energy cost for growth is proportional to growth, and done initially:

$$C_{n,t} (R_{n,t}, \alpha_{n,t}) = \frac{\Delta_{n,t}}{ERoEI_{n,t}} \alpha_{n,t} R_{n,t} \text{ if } \alpha_{n,t} \geq 0$$

- Long-term replacement cost is (i) proportional and (ii) annualized

$$M_{n,t} (R_{n,t}) = \frac{1}{ERoEI_{n,t}} R_{n,t}$$

$$E_0 = 1$$

$$B_0 = 0.85E_0$$

$$R_{1,0} = 0.01E_0$$

$$\sum_{n=2}^N R_{n,0} = 0.14E_0$$

$$ERoEI_{1,t} = 9$$

$$\Delta_{1,t} = 20$$

$$\sigma_t = 14$$

Constant growth
if possible, else
max admissible

Fig. 2. Scenario “peak at time t=0”

Fig. 3. Scenario “plateau at time t=0”

Fig. 4. Scenario “peak at time t=20”

Fig. 5. Scenario “plateau at time t=20”

Modeling the transition

- Increasing the ERoEI parameter

$$\forall t \in \{0, \dots, T-1\}, ERoEI_{1,t} = 9 + \frac{t}{T}(12 - 9)$$

So?

A few suggestions

- What kind of decisions can be suggested by such a « rough model »?
 - Price may not always be a good indicator
 - Pay attention to the ERoEI
 - Energy efficiency: « do better with less »
- The energy transition is a global process: how to prioritize actions?
 - Back to Maslow

Epilogue

During the collapse of the Roman Empire, the quality of the food (measured from bones) improved (this may be explained by the fact that the pressure of the Empire on agriculture decreased with the collapse)

This is an example of « good news » that may come with the switch from a society model to another...

... and I believe this will be the case for the energy transition
